

KasiShares

Executive readiness brief

Where the international USDT share-purchase system stands, what must still be proven, and the shortest safe path to an invited pilot.

50-60%	3	0
Engineering foundation in place	Critical bridges before money moves	Live campaigns or invitations

Current state: the engine exists; the gearbox is missing

The work is not a wholesale rebuild. It is a controlled integration of existing payment, KYC and share components.

Workstream	Evidence	Readiness
International KYC	KaSiHub international KYC policy and approval gate exist; ClickUp marks the work in progress.	In progress
USDT payment foundation	Server-controlled wallets, intent expiry, idempotency, transaction-hash replay protection and payment state history are present.	Foundation built
BSC/TRON verification	Chain adapters parse transaction evidence, exact token transfer logs and confirmations. Live RPC configuration and controlled proof remain.	In progress
Private campaign flow	Admin campaigns, invitation links and payment-instruction isolation exist. No live campaign or invitation is active.	Prototype ready
Share settlement	The current presale payment path is separate from the general payment-intent machinery; verified evidence is not yet the sole trigger for certificate issuance.	Not connected
Phase 1 BOGO	Existing business rule is confirmed: BOGO applies only to Phase 1. Paid-versus-issued share accounting still needs to be joined to settlement.	Design gap

Why the split matters

A provider receiving USDT is not the same thing as approving a share sale. Remitano may receive inbound funds on approved wallets, but KaSiHub must independently verify the on-chain transfer and record the settlement exactly once.

The three critical bridges

These are the remaining controls that stop a payment screen from becoming an uncontrolled sale.

1	Eligibility gate	International buyer is KYC-verified before an order or payment intent can proceed. The current general payment intent gate exists; the presale path still needs to use it.
2	Evidence to settlement	A submitted transaction hash is checked on the selected chain for exact USDT contract, receiver, amount, execution status and confirmations. Only that result may settle the order.
3	Settlement to shares	One idempotent transaction records settlement, applies Phase 1 BOGO correctly, decrements inventory, creates the certificate and leaves an audit trail. Retries must not create extra shares.

Target operating flow

Verified international member	Private invitation	Remitano receiving wallet	On-chain verification	KaSiHub settlement + certificate
-------------------------------	--------------------	---------------------------	-----------------------	----------------------------------

Important boundary

Remitano is allowed to be the inbound receiver. It is not the authority that determines whether shares are issued. The authoritative fact remains: KaSiHub has independently verified and settled the exact on-chain payment.

Recommended path to an invited pilot

The sequence below prevents a public launch from becoming the test environment.

Now	Lock commercial inputs	Approve Phase 1 price currency/USDT conversion policy, issued-share BOGO rule, exact approved USDT contracts, receiving wallets, confirmation thresholds, order expiry and high-value review threshold.
Build	Connect the three bridges	Use international KYC gate in the presale route; make the chain verifier settle the share order; implement atomic BOGO certificate issuance and compensation for failures.
Prove	Run controlled transfers	Configure production-grade RPC access and conduct low-value TRON and BSC transfers. Verify normal, delayed-confirmation, wrong-token, wrong-wallet, underpayment and duplicate-hash cases.
Pilot	Invite a very small cohort	Use caps, manual reconciliation, explicit operator approvals and daily monitoring. Expand only after certificates, ledger, reports and support playbook agree.

Executive decisions required before money moves

- Approve whether the Phase 1 price remains USD-denominated with a server-controlled USDT quote, or becomes a fixed USDT price.
- Approve the BOGO contract: one paid share creates two issued shares, and define what inventory quantity that consumes.
- Approve exact BSC and TRON USDT contracts, receiving wallets, confirmation thresholds and the pilot cap.
- Approve the pilot owner, reconciliation cadence and stop conditions.

Source basis

Repository architecture and implementation review, plus KaSiHub Integrations ClickUp tasks covering payment foundation, international KYC, blockchain attestation, settlement, KasiShares integration and Remitano scope. Status is an engineering readiness view, not legal, financial or regulatory advice.
