

Remitano as the receiving point for KaSiShares purchases.

A controlled path for international USDT income: two locked receiving routes, verified payment evidence, and no automatic share issuance.

THE OBJECTIVE

Accept USDT safely without turning an exchange deposit into a share ledger.

Buyers may pay an approved obligation via Remitano. KaSiHub independently verifies the transaction and only then permits the controlled allocation workflow.

2

separate network routes: TRON and BNB Smart Chain

THE KEY DISTINCTION

Money received $\neq$ shares issued.

Receiving USDT proves neither identity, eligibility, allocation availability, nor legal acceptance. Those gates remain inside KaSiHub.

This avoids a dangerous shortcut where a provider callback or wallet deposit automatically changes ownership records.

What is already prepared vs. what remains

PREPARED

Two-network model

TRON and BSC are supported as distinct payment networks.

PREPARED

Provider-aware routes

Receiver configurations can be labelled as Remitano and locked per network.

NEXT

Remitano adapter

Secure provider connection, event verification, and reconciliation.

Non-negotiable security boundary

Do not use credentials copied from ClickUp. Reissue them and place the replacement only in Encore managed secrets. Provider keys, deposit addresses, and webhook secrets do not belong in browser code, logs, tickets, or repositories.

The safe flow

The buyer never chooses an arbitrary wallet. KaSiHub binds the obligation to one approved network, token, receiver, amount, and expiry.

What Remitano does

- Provides the controlled collection endpoint or payment-gateway charge.
- Returns provider events / payment status where supported.
- Receives the USDT into the approved route.

What KaSiHub must still prove

- Buyer identity and eligibility.
- Correct USDT contract, network, receiver, amount, and confirmations.
- One-time reconciliation and an authorised allocation decision.

Two routes, never interchangeable

BUYER PAYMENT ROUTE	LOCKED TO	WHY IT MATTERS
USDT-TRC20 TRON	One verified Remitano receiver, approved USDT contract, confirmation threshold.	A TRON transaction must not be treated as a BSC payment.
USDT-BEP20 BNB Smart Chain	Different verified Remitano receiver, approved USDT contract, confirmation threshold.	Prevents cross-chain loss and makes reconciliation deterministic.

Stop conditions

Wrong network, wrong token contract, wrong recipient, short payment, expired obligation, duplicate event, or insufficient confirmations all stop automatic progression and enter an operator review path.

Readiness is a chain, not a checkbox.

The provider route is the first leg. The payment must survive technical, financial-control, and legal-operational checks before the public presale opens.

Inputs required from Remitano / the operator

INPUT	WHY IT IS NEEDED	OWNER
Business/API access enabled	Lets the server create or reconcile provider-side payment requests.	Remitano account owner
Fresh API credentials and callback secret	Authenticates server-to-server requests and signed events.	Account owner + platform operator
Exact TRON and BSC receiver configuration	Binds each buyer obligation to a safe, verifiable destination.	Remitano account owner
USDT token contract and confirmation policy	Rejects lookalike tokens and premature deposits.	Remitano + platform operator
Approved share-offer terms and allocation authority	Governs whether a verified payment can progress to allocation.	KaSiShares authorised operator

What the team should decide first

Use payment-gateway charges if Remitano supports them for this account. They give each buyer an explicit provider-side reference. Use static deposit routes only if they are confirmed as appropriate for the business and paired with strict KaSiHub transaction matching.

Four release stages

STAGE 1

Provider onboarding

Confirm account permissions, choose charge vs. receiver model, reissue credentials, and store replacements in Encore secrets.

Exit: no secrets exposed; provider contract known.

STAGE 2

Route configuration

Register the exact TRON and BSC receivers with their approved contracts and confirmation thresholds.

Exit: two routes are independently testable.

STAGE 3

Adapter and reconciliation

Add server-only provider client, signed callback verification, idempotency, transaction matching, and operator review states.

Exit: test suite proves every rejection path.

STAGE 4

Staging pilot → production

Run one small controlled payment per network, validate financial records, then release through a rollback-safe deployment.

Exit: public collection is enabled only after evidence.

Acceptance test matrix

TEST	EXPECTED RESULT
Correct TRC20 / correct amount / confirmed	✓ Reconciles once; enters allocation workflow.
Correct BEP20 / correct amount / confirmed	✓ Reconciles once; enters allocation workflow.
Wrong chain, token, receiver, or amount	✗ Cannot settle; retained for controlled support review.
Duplicate provider callback or transaction replay	✗ Idempotency blocks a second credit.
Payment before KYC / after expiry	✗ No allocation; operator process only.

The immediate next move

GET THESE FACTS FIRST

Securely obtain the approved Remitano collection model, freshly issued server credentials, and the exact TRON/BSC receiving configuration. That unlocks the adapter build without guessing about wallets, providers, or where investor funds are sent.
