

TRON / TRC20 USDT IMPLEMENTATION HANDOFF

A controlled first
payment rail for
KaSiHub

The objective

Enable one controlled USDT payment rail without creating a KaSiHub token, deploying a custom smart contract, or accepting funds before the security, custody and compliance gates are approved.

What you need to decide or supply

YOU: OWNER CONTROL	WHY IT CANNOT BE INVENTED
1. Approve TRON / TRC20 as the first and only enabled network.	Each network creates a separate operational, fraud and reconciliation surface. Start with one.
2. Supply the public receiving address for the approved custody wallet. Never provide a private key or seed phrase.	The address is the controlled destination that every payment intent will lock and verify.
3. Name the custody model and approvers: who controls the wallet, who may sweep funds, and how recovery works.	A payment route without accountable custody is not a production asset; it is a liability.
4. Approve a server-side RPC provider account and credential owner (for example, TronGrid).	The verifier needs independent blockchain reads. API keys are persistent access credentials and must remain in managed secrets.
5. Obtain legal/compliance approval for the issuer, investor eligibility, terms, disclosures and go-live gate.	Technical settlement evidence is not legal issuance authority.

Official technical references

- **Official USDT TRC20 contract:** TR7NHqjeKQxGTCi8q8ZY4pL8otSzglJ6t
- **Tether supported protocols:** <https://tether.to/en/supported-protocols/>
- **TRON developer documentation:** <https://developers.tron.network/docs/networks>
- **TRON multi-signature/account permissions:** <https://developers.tron.network/docs/multi-signature>
- **RPC provider:** <https://www.trongrid.io/>

Important: do not substitute a token address from a search result. The verifier must use the exact approved official contract for the configured network.

What KaSiHub will do after you provide the three operational inputs

KASIHUB EXECUTION	SUCCESS CONDITION
Configure the TRON receiving route in staging, locked to the official USDT contract and your approved public address.	The route remains non-active and cannot be used by a live campaign.
Store the RPC credential only in managed server-side secrets and connect the independent chain verifier.	No credential reaches the browser, source control or application logs.
Create a payment intent per reservation with the exact network, token, receiver, amount and expiry.	The buyer cannot alter settlement terms from the browser.
Verify chain evidence before settlement: successful transfer, official token, correct receiver, exact amount, confirmation depth and no hash reuse.	A submitted transaction hash remains untrusted until independently confirmed.
Run no-money and controlled small-value rehearsals, then provide auditable results and rollback evidence.	No campaign activation is implied by a passing technical test.

The handoff message to send

Approved first rail: TRON / TRC20. **Receiving address:** [public address only]. **Custody owner and approvers:** [names/roles]. **RPC provider and secret owner:** [provider + secure secret reference]. **Authority:** configure staging only; do not activate a campaign or accept funds.

Boundary

Do not send private keys, seed phrases, real customer documents or real funds. A custom KaSiHub smart contract is not required for this direct USDT settlement design. It becomes a separate audited project only if the business chooses on-chain escrow, automated refunds/allocation, or tokenised securities.
